

# Kamailio® - Variables and Transformations

Henning Westerholt

Kamailio World

September 2021 - Online

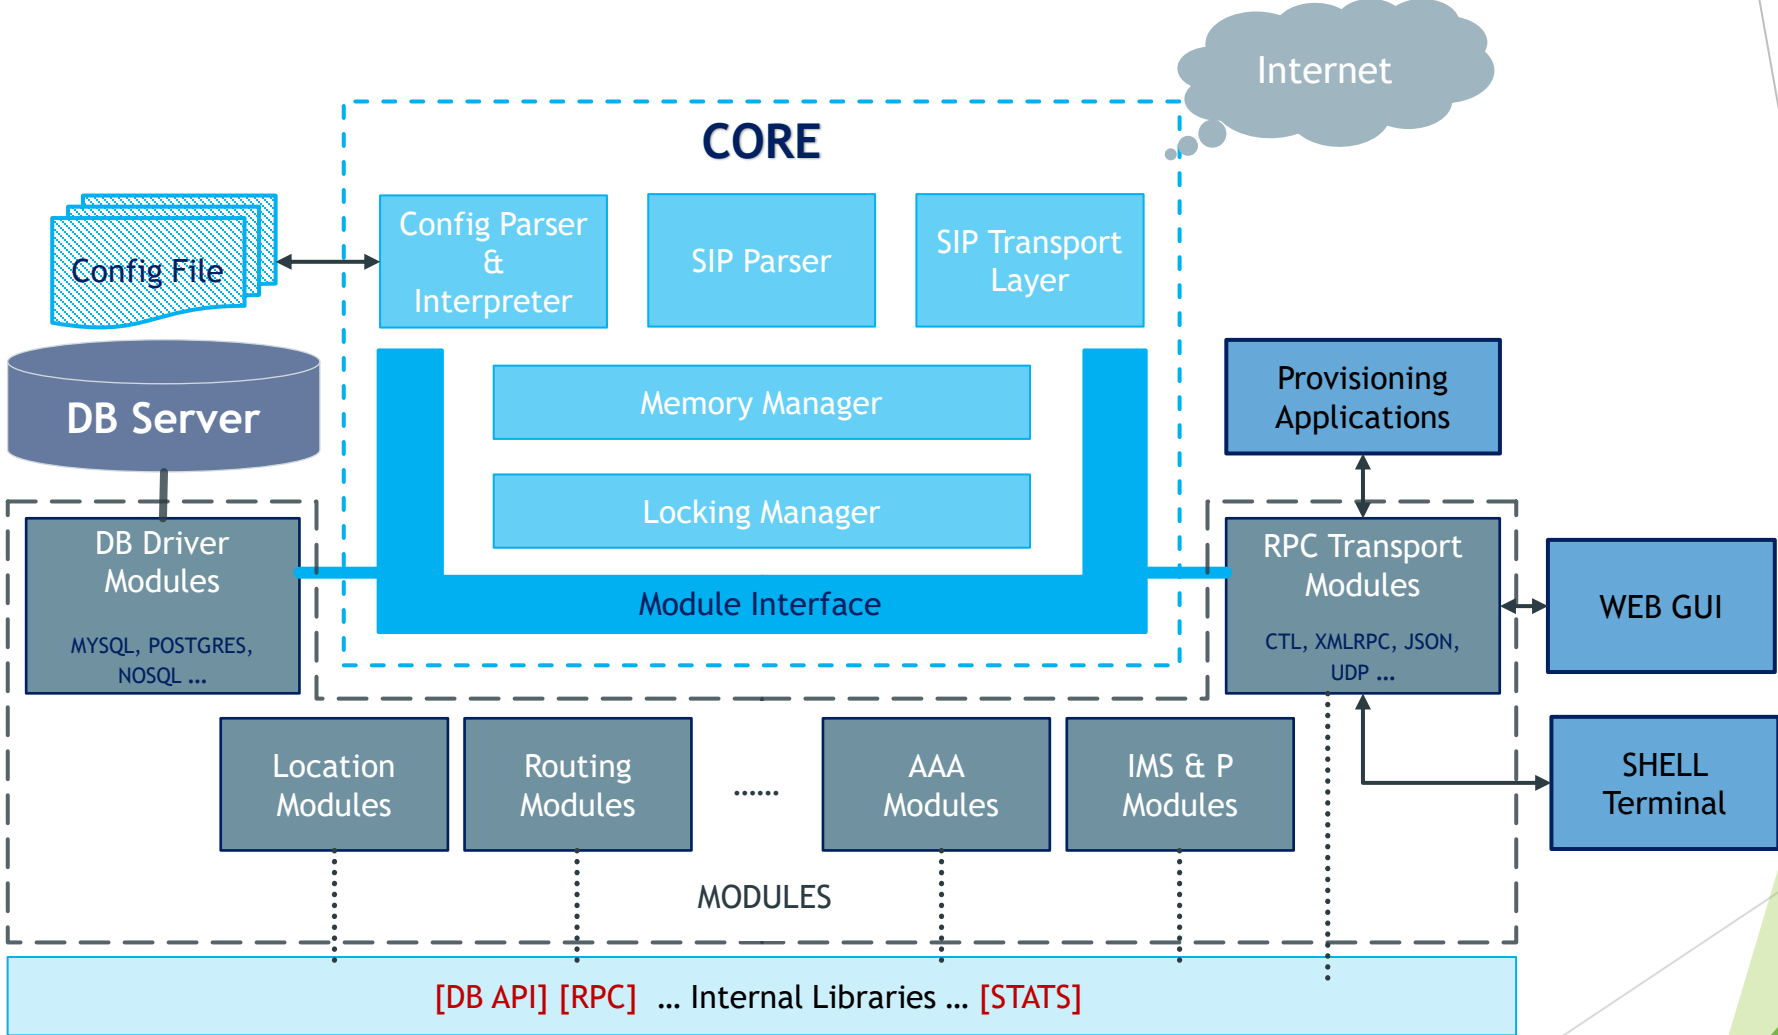

# Agenda

- ▶ About
- ▶ Background
- ▶ Pseudo-variables
- ▶ Transformations
- ▶ Contact

# About GILAWA

- ▶ We offer services for Real-Time Communication platforms
  - ▶ Consulting and Management
  - ▶ Administration/Developer trainings
  - ▶ Development and IT Operations
- ▶ Kamailio experience since 2007
- ▶ Independent and neutral service provider
  - ▶ No own end-user products
  - ▶ No vendor contracts
- ▶ Our customer are Internet Service Providers and Telephone Provider
- ▶ Mainly in Germany, Europe and North-America

# Kamailio overview

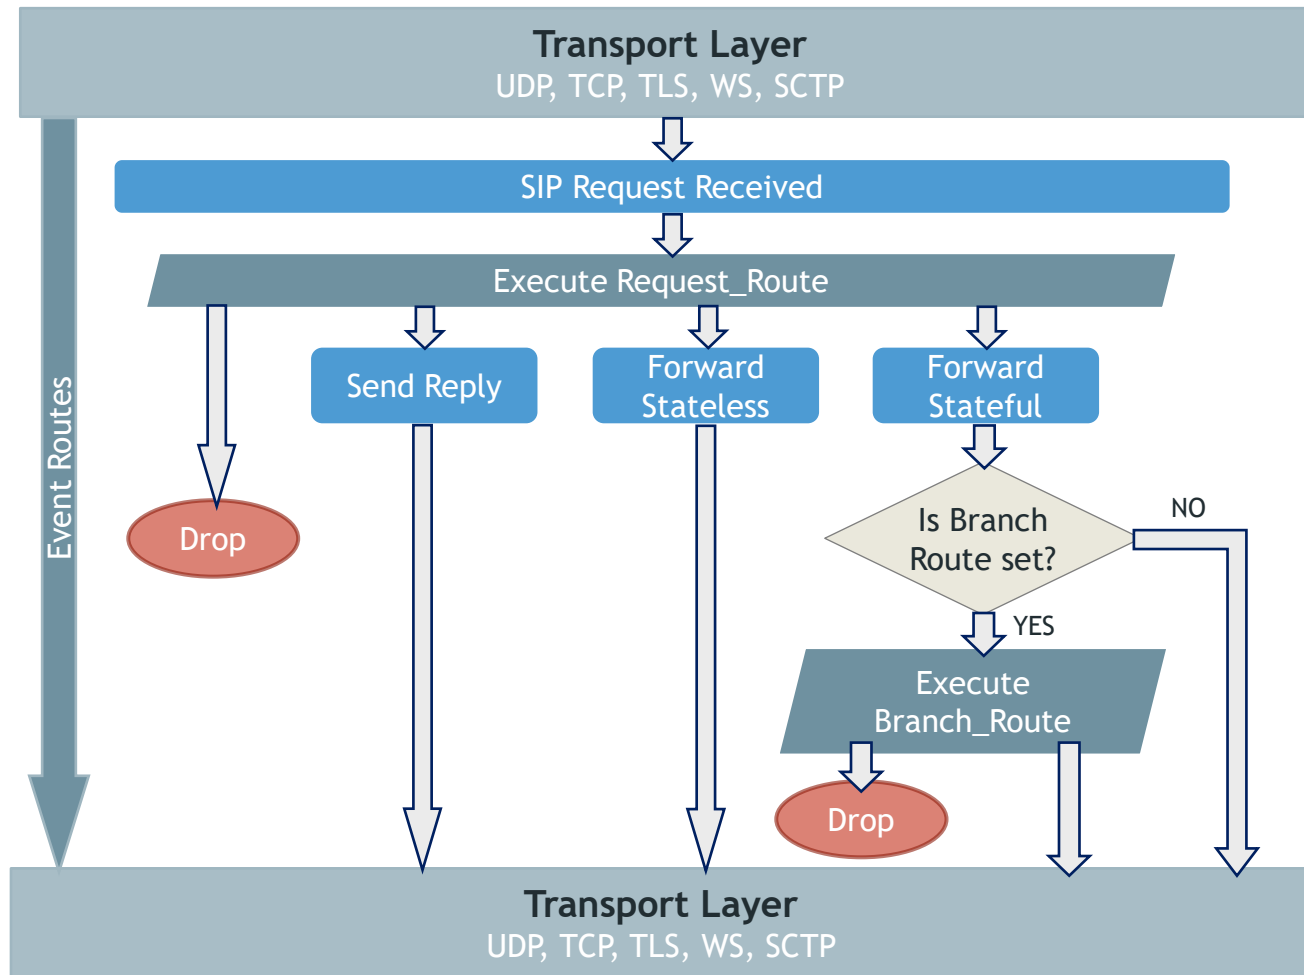

# Kamailio configuration structure

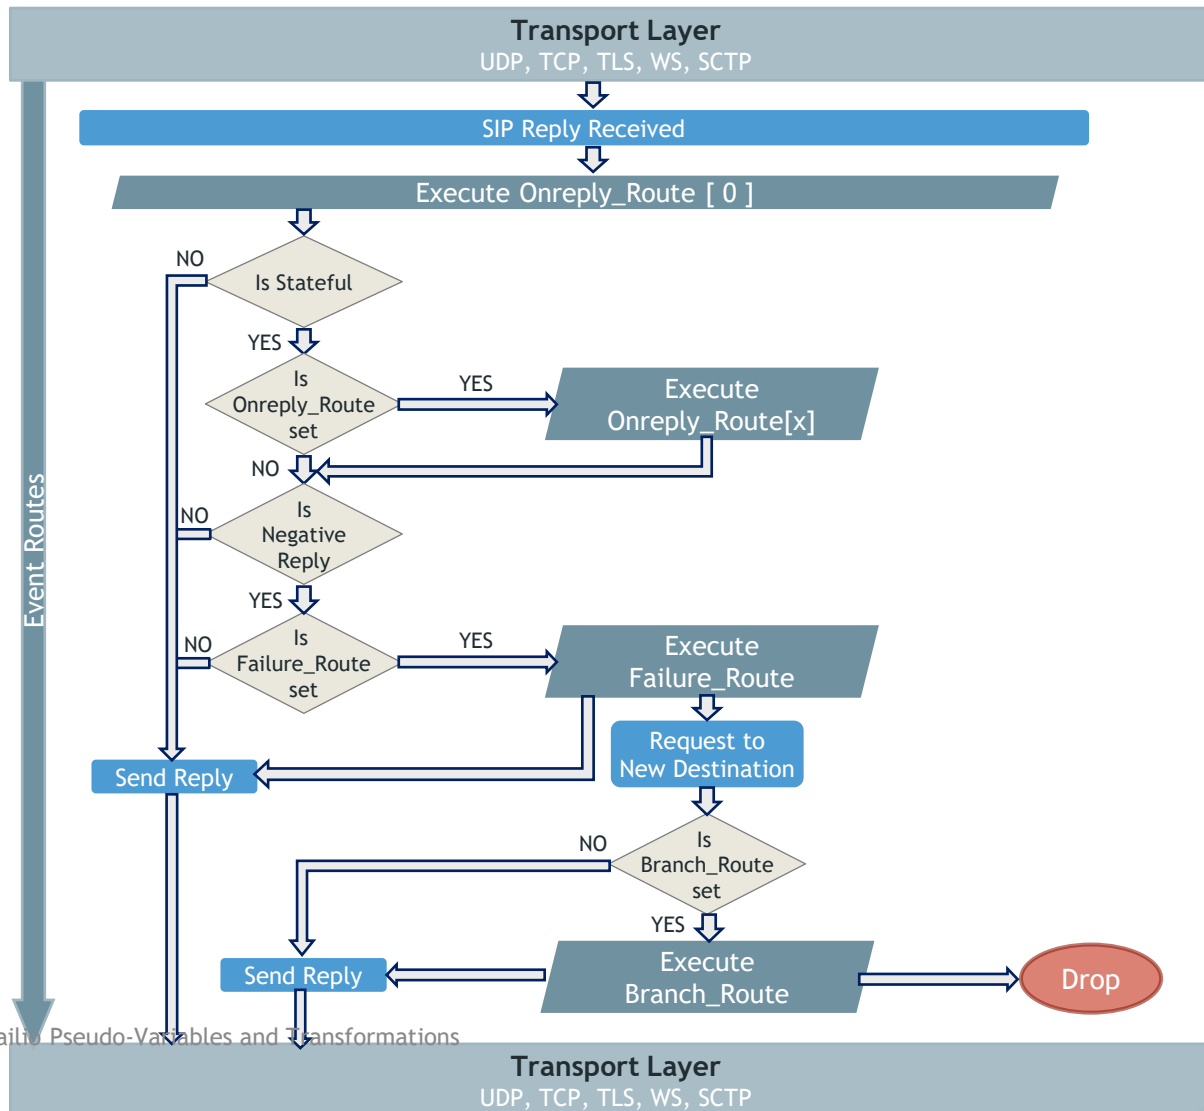

- ▶ The Kamailio configuration can be structured in different main sections
  - ▶ Pre-Processing definitions and includes
  - ▶ Global options
  - ▶ Module loading
  - ▶ Module parameter
  - ▶ Main request route
  - ▶ Additional routes
- ▶ Pseudo-Variables and Transformations are mainly used in the configuration routes

# SIP request processing

# SIP reply processing

# Small history

- ▶ Pseudo-Variables were created to generalize and standardize the existing „special“ variables in Kamailio configuration
  - ▶ Before variables would look similar to other key words of the scripting language
  - ▶ Examples: “uri” to access request URI, “src\_ip” to access source IP
- ▶ First PVs were included in OpenSER 0.9.4 (2005) and extended substantially
- ▶ Kamailio 1.5.0 moved PVs (and transformations) from the core to pv module
- ▶ Transformations were added to provide a modular and extensible way to access certain information and to format them in a certain way
- ▶ They were added a bit later for OpenSER 1.2.0 (2007)
- ▶ Kamailio 1.5.0 (2009) introduced the first main generic module user -htable

# What are pseudo-variables

- ▶ The term “pseudo-variable” is used for special tokens that can be given as parameters to different script functions
- ▶ They will be replaced with a value before the execution of the function
- ▶ The majority of PVs are read-only, but many of them are also read-write
- ▶ The beginning of a “pseudo-variable” is marked by the character “\$”
- ▶ Pseudo-variables are implemented by various modules, most of them are provided by the „pv“ module
- ▶ They should be supported by most core and module script functions
- ▶ Usually all of them are documented in the wiki for the different versions
  - ▶ E.g., <https://www.kamailio.org/wiki/cookbooks/5.5.x/>
- ▶ Note about performance

# Pseudo-variables usage

- ▶ From default Kamailio configuration
- ▶ 

```
if(is_method("INVITE")) {  
    if($avp(oexten)==$null) return;  
    $ru = "sip:" + $avp(oexten) + "@" + $sel(cfg_get.voicemail.srv_ip)  
        + ":" + $sel(cfg_get.voicemail.srv_port);  
} else {  
    if($rU==$null) return;  
    $ru = "sip:" + $rU + "@" + $sel(cfg_get.voicemail.srv_ip)  
        + ":" + $sel(cfg_get.voicemail.srv_port);  
}
```

# Kamailio (pseudo-)variables (1/4)

- ▶ Flags (normal, branch flags) - \$mf
- ▶ „Classic“ variables (uri, src\_ip etc..)
- ▶ Access to SIP message content
  - ▶ \$ru - request URI
  - ▶ \$fU - From header user name part, \$td - To header domain part
  - ▶ \$hdr - access to arbitrary headers
  - ▶ There are many more, for most well-known headers are PVs available
- ▶ Access to SIP replies
  - ▶ \$rr - reply reason phrase or \$s - reply code

# Kamailio pseudo-variables (2/4)

## ▶ Transactional

- ▶ `$avp` - Attribute-Value-Pair: transactional variable
- ▶ `$xavp` - extended AVP: again transactional, supports index/field access, Example: `$xavp(person=>fname)=„John“`; `$xavp(person=>lname)=„Doe“`;
- ▶ `$xavi` - similar to `$xavp` but case insensitive for keys
- ▶ `$xavu` - similar to `$xavp` but unique for values, no indexes

## ▶ In-memory

- ▶ `$sht` - hash table (htable module)
- ▶ `$shv` - variable shared between processes
- ▶ `$var` - variable individual per process with default 0
- ▶ `$vn` - similar to `$var` but with default `$null`

# Kamailio pseudo-variables (3/4)

- ▶ Dialog stateful
  - ▶ `$dlg` - attributes about the processed dialog
  - ▶ `$dlg_ctx` - dialog context attributes about the processed dialog
  - ▶ `$dlg_var` - store and retrieve customer variables for the processed dialog,  
Example: `$dlg_var(provider)=„carrier1“; if ($dlg_var(provider) == „carrier1“) {..}`
- ▶ Time handling
  - ▶ `$time` - access to different time components
  - ▶ `$TS` - current unix timestamp and others
- ▶ Access to environment
  - ▶ `$env` - access to linux environment variables
  - ▶ `$C` - terminal foreground and background colors

# Kamailio pseudo-variables (4/4)

- ▶ Kamailio attributes
  - ▶ `$def` - access defined pre-processor values
  - ▶ `$version` - output Kamailio version in different formats
  - ▶ `$stat` - return the value of statistic items
  - ▶ `$mb` - message buffer
- ▶ Other important module interfaces
  - ▶ `$T` - access to current transactions
  - ▶ `$T_branch` - access to current branch attributes
  - ▶ `$uac_req` - can be used to create SIP requests
  - ▶ `$http_req` - can be used to create HTTP requests

# Use cases PVs

- ▶ Evaluate User-Agent string and block certain devices
  - ▶ Use `$ua` with regular expression match
- ▶ Increase performance for slow database operations
  - ▶ Use `$sht` to save DB query results
- ▶ Performance evaluations of your `cfg`
  - ▶ Use `$TV` for micro-seconds timestamp (note: benchmark module has more options)
- ▶ Multi-homed setup networks routing
  - ▶ Use `$fs` to specify outgoing send socket (note: now possible with send socket name)
- ▶ Access data from different sources
  - ▶ `sqlops` for SQL database, `$redis` for Redis DBs etc..

# What are transformations

- ▶ A transformation is basically a function that is applied to a pseudo-variable (PV) to get a property of it
- ▶ The value of PV is not affected at all, they are read-only operations
- ▶ Provide a modular system, to prevent the addition of hundreds of special PVs
- ▶ Transformations are implemented by various modules, most of them being in pv module
- ▶ Transformations are intended to facilitate access to different attributes of PV
- ▶ A transformation is represented in between '{' and '}' and follows the PV name
- ▶ When using transformations, the PV name and transformations must be enclosed in between '(' and ')', following the \$ sign

# Other ways of evaluating variables

- ▶ There exists of course other methods to evaluate (pseudo-)variables
- ▶ Like textops and texpopsx, siputils modules etc..
- ▶ From SER we also inherited the „select“ Framework
- ▶ They can be accessed with \$sel
- ▶ Selects provide a sub-set of PV functionality
- ▶ They are not further extended, but used in a few places

# Transformation usage

- ▶ Length of From URI
  - ▶ `$(fu{s.len})`
- ▶ Several transformation can be applied the same time to a PV
  - ▶ Length of escaped 'X-SBC' header body
  - ▶ `$(hdr(X-SBC){s.escape.common}{s.len})`

# Useful Transformations (1 / 3)

- ▶ String operations
  - ▶ `{s.len}`, `{s.int}`, `{s.trim}`
- ▶ Data conversions
  - ▶ `{s.encode.7bit}`, `{s.encode.base64url}`
- ▶ Escaping
  - ▶ `{s.escape.common}`, `{s.escape.user}` (note: there is also `{sql.val}` available)
- ▶ URI-transformations, to access all kind of data from a SIP URI
  - ▶ `{uri.user}`, `{uri.host}`, `{uri.port}` etc..
  - ▶ Transformation for special use cases available, e.g. `{uri.saor}`
  - ▶ `$var(ouri) = "sip:alice@server.com:5060;nat=yes;transport=tcp;line=xyz";`
  - ▶ `$var(suri) = $(var(ouri){uri.saor}); # => "sip:alice@server.com"`

# Useful Transformations (2/3)

- ▶ Parameters List Transformations, to access values from a concatenated string
  - ▶ {param.value,name[, delimiter]}, {param.name,index[, delimiter]}
  - ▶ "a=1;b=2;c=3"{param.value,c} = "3"
- ▶ Name-address Transformations, to access values from a “Display name” URI
- ▶ To-Body Transformations, to access values from more complex headers like To
  - ▶ {tobody.params} - the parameters can be then evaluated further
- ▶ HTTP URL Transformation
  - ▶ {url.path}, {url.querystring}
- ▶ URI Alias Transformations
  - ▶ {urialias.encode}, {urialias.decode}

# Useful Transformations (3/3)

- ▶ JSON Transformation
  - ▶ `{json.parse}`
- ▶ Hash Transformations
  - ▶ `{s.sha256}`, `{s.md5}`
- ▶ Select operations
  - ▶ `{s.select,index,separator}`
- ▶ Regular expression
  - ▶ `{re.subst,expression}`
  - ▶ # Assign Request-URI user to PV, where every 'A' has been replaced by 'a'
  - ▶ `$var(user) = ${rU{re.subst,/A/a/g}};`

**GILAWA**

Thank you
